Abstract

The sheer volume of unstructured multimedia data (e.g., texts, images, videos) posted on the Web during events of general interest is overwhelming and difficult to distill if seeking information relevant to a particular concern. We have developed a comprehensive system that searches, identifies, organizes and summarizes complex events from multiple data modalities. It also recommends events related to the user’s ongoing search based on previously selected attribute values and dimensions of events being viewed. In this paper we briefly present the algorithms of each component and demonstrate the system’s capabilities.

1 Introduction

Every day, a vast amount of unstructured data in different modalities (e.g., texts, images and videos) is posted online for ready viewing. Complex event extraction and recommendation is critical for many information distillation tasks, including tracking current events, providing alerts, and predicting possible changes, as related to topics of ongoing concern. State-of-the-art Information Extraction (IE) technologies focus on extracting events from a single data modality and ignore cross-media fusion. More importantly, users are presented with extracted events in a passive way (e.g., in a temporally ordered event chronicle (Ge et al., 2015)). Such technologies do not leverage user behavior to identify the event properties of interest to them in selecting new scenarios for presentation.

In this paper we present a novel event extraction and recommendation system that incorporates advances in extracting events across multiple sources with data in diverse modalities and so yields a more comprehensive understanding of collective events, their importance, and their inter-connections. The novel capabilities of our system include:

- **Event Extraction, Summarization and Search**: extract concepts, events and their arguments (participants) and implicit attributes, and semantically meaningful visual patterns from multiple data modalities, and organize them into Event Cubes (Tao et al., 2013) based on Online Analytical Processing (OLAP). We developed a search interface to these cubes with a novel back-end event summarization component, for users to specify multiple dimensions in a query and receive single-sentence summary responses.

- **Event Recommendation**: recommend related events based on meta-paths derived from event arguments, and automatically adjust the ranking function by updating the weights of dimensions based on user browsing feedback.

2 Overview

2.1 System Architecture

The overall architecture of our system is illustrated in Figure 1. We first extract textual event information, as well as visual concepts, events and patterns from the raw multimedia documents to construct event cubes. Based on the event cubes, the search interface (Figure 2) returns the document that best
matches the user’s query as the first primary event for display. A query may consist of multiple dimensions (Figure 3). The recommendation interface displays multiple dimensions and rich annotations of the primary event, and recommends similar and dissimilar events to the user.

2.2 Data Sets

To demonstrate the capabilities of our system, we use two event types, Protest and Attack, as our case studies. We collected the following data sets:

- **Protest**: 59 protest incidents that occurred between January 2009 and December 2010, from 458 text documents, 28 images and 31 videos.
- **Attack**: 52 attack incidents that occurred between January 2014 and December 2015, from 812 text documents, 46 images and 6 videos.

3 Event Cube Construction and Search

3.1 Event Extraction
We apply a state-of-the-art English IE system (Li et al., 2014) to jointly extract entities, relations and events from text documents. This system is based on structured perceptron incorporating multiple levels of linguistic features. However, some important event attributes are not expressed by explicit textual clues. To enrich the profile of each protest event, the system identifies two additional implicit attributes that derive from social movement theories (Della Porta and Diani, 2009; Furusawa, 2006; Dalton, 2013):

- **Types of Protest**, including demonstration, riot, strike, boycott, picket and individual protest.
- **Demands of Protest**, indicating the hidden behavioral intent of protesters, about what they desire to change or preserve, including pacifist, political, economic, retraction, financial, religious, human rights, race, justice, environmental, sports rivalry and social.

We annotated 92 news documents, 59 of which contained protests, to learn a set of heuristic rules for automatically extracting these implicit attributes from the IE outputs of these documents.

3.2 Event Cube Construction and Search
Event extraction helps in converting unstructured texts into structured arguments and attributes (dimensions). However, a user may still need to “drill down,” searching back through many documents and changing query selections before finding an item of interest. We use EventCube (Tao et al., 2013) to effectively organize and efficiently search relevant events, and measure event similarity based on multiple dimensions. EventCube is a general online analytical processing (OLAP) framework for importing any collection of multi-dimensional text documents and constructing text-rich data cube. EventCube differs from traditional search engines in that it returns Top-Cells, where relevant documents are aggregated by dimension combinations.

We regard each event as a data point associated with multiple dimension values. After a user inputs a multi-dimensional query in the search interface (Figure 2), we build inverted index upon the dimensions in Event Cube to return related events, which provides much more flexible matching compared to keyword search.

4 Multi-media Event Illustration and Summarization
After the search interface retrieves the most relevant event (‘primary event’), the user will be directed to the recommendation interface (Figure 2b) and can start exploring various events. The user’s initial query is displayed at the top (gray bar) and is updated to capture new user selections. The number of events that match the user’s initial query and the number of documents associated with the primary event are displayed in the gray bar, at the far right side. In addition to text IE results, we apply the following multi-media extraction and summarization techniques to illustrate and enrich event profiles.

4.1 Summarization
From each set of relevant documents, we apply a state-of-the-art phrase mining method (Liu et al., 2016) to mine top-$k$ representative phrases. Then we construct an affinity matrix of sentences and apply spectral clustering to find several clustering centers (i.e., representative sentences including the most important phrases) as the summary. The user is also provided two options to show the original documents and the document containing the summary.

4.2 Visual Information Extraction
For each event, we retrieve the most representative video/image online using the key-phrases such as date, location and entities as queries. Videos and images are often more impressive and efficient at conveying information. We first apply a pre-trained convolutional neural network (CNN) architecture (Kuznetsova et al., 2012) to extract visual concepts from each video key frame based on the EventNet concept library (Ye et al., 2015). For example, the extracted visual concepts “crowd on street, riot, demonstration or protest, people marching” appear when the user’s mouse is over the video of the primary event (Figure 2b). Then we adopt the approach described in (Li et al., 2015) which applies CNN and association rule mining technique to generate visual patterns and extract semantically meaningful relations between visual and textual information to name the patterns.
5 Event Recommendation

We rank and recommend events based on **meta paths** (Sun et al., 2011), by representing the whole data set as a heterogeneous network, that is composed of multi-typed and interconnected objects (e.g., events, location, protesters, target of protesters). A meta path is a sequence of relations defined between different object types. For protest events, we define six meta paths: “event-date-event”, “event-location-event”, “event-target of protest-event”, “event-protesters-event”, “event-type of protest-event” and “event-demand of protest-event”; and four meta paths for attack events: “event-date-event”, “event-location-event”, “event-attackers-event” and “event-type of attack-event”.

The similarity between two events is the weighted sum of the six meta path similarities. The weights are assigned dynamically by the user’s activity:

- When the user clicks on a certain image/video: assign 1.0 to all meta-path similarities.
- When the user clicks on a certain dimension X: 1.0 for the similarity based on Event-X-Event, and 0.2 to other meta-paths.

To illustrate the meta paths, the dimension names of recommended events are highlighted if they share the same dimensions with the primary event. Moreover, the system is switchable between recommending the most similar and most dissimilar events with a toggle button that the user can click.

6 Conclusions and Future Work

In this paper we present a cross-media event extraction and recommendation system which effectively aggregates and summarizes related complex events, and makes recommendations based on user interests. The current system interface incorporates a medium-level human agency (the capacity of an entity to act) by allowing a human user to provide relevance feedback while driving the browsing interests by multi-dimensional recommendations. We plan to follow the cognitive fit theory (Vessey, 1991) and conduct a series of human utility evaluations to formally quantify the impact of each new component and each data modality on enhancing the speed and quality of aggregating and summarizing event-related knowledge, detecting conflicts and errors, and generating alerts.
